How it is built

For Stylified's owner and for anyone you ask to review the solution. It says what exists, what is built in this project, and where we are still working.

01 Overview

Stylified gets its own workspace on Verity's hosted platform. The workspace is a set of screens and rules for the piece-rate cycle, on top of a shared foundation that provides sign-in, roles, an audit trail, files, notifications and company isolation.

EXPERIENCE	Web application for desktop, tablet and phone, dark and light themes. Supervisor screens are designed phone-first. Hindi and English labels on entry and supervisor screens.
PIECE-RATE MODULE	Lots, bundles, stages, karigars and rates, issues and returns, rework, shortages, wages and money, approvals, day close, reports. Every change is a *command* with its own checks; every screen reads through a *query*.
PLATFORM FOUNDATION	Company isolation, identity and memberships, roles built from permissions, an audit trail, an event log, file storage, notifications, numbering, configuration.
DATA AND HOSTING	A relational database with row-level security forced on every Stylified table, file storage, application hosting in an Indian region, backups.

02 Hosting

PART	WHERE AND HOW
Application	Hosted serverless application, deployed to the Mumbai region (configured in the deployment settings)
Database	Managed PostgreSQL in the Mumbai region, reached through a connection pooler in transaction mode. The application connects as a restricted role that cannot bypass row-level security
Files	Object storage with the same company isolation; used for photographs
Sign-in	The platform's identity service; passwords never reach Verity's own tables
Environments	A demonstration workspace with fictional data and Stylified's own workspace are separate tenants. Nothing is shared between them

PART	WHERE AND HOW
Deployment shape	Verity's shared hosted deployment (one application and database for many companies, each isolated as in section 3). A dedicated instance on Stylified's own Vercel and Supabase accounts is **not part of this solution**: see below

If Stylified later wants its own accounts

Running Verity on a customer's own Vercel and Supabase accounts is feasible but not yet built or validated. Our research lists what must be done first: scripting the creation of the restricted database role the application connects as, a scripted first-operator and first-company setup on a fresh Supabase project, a scheduled-jobs setup per instance, separate file and database backups, a release and migration channel for more than one instance, and a support model without a shared console. A rehearsal on throwaway accounts must pass before any real data moves. Provider plans must allow business use (Vercel Pro and Supabase Pro are the minimum; free plans are not suitable). We will quote the move separately once this is done; until then the isolation, backup and security statements in this document describe the shared hosted deployment only.

Provider names and plans can change over the life of the service; the data stays in an Indian region and the isolation rules below do not change.

03 Company isolation

- Every Stylified record carries the company it belongs to. The database itself refuses to return or accept a row for another company: row-level security is **forced** on each table and the company is set for each request from the signed-in user's verified membership, **never from anything the browser sends**.
- If no company is set, a query returns nothing and a write is rejected: isolation fails closed.
- The platform checks at startup that its database role is one that cannot bypass these rules, and refuses to run otherwise. An automated test proves that one company cannot read another's data.

04 Roles and permissions

- A permission is an action on a kind of record within a scope (for example "issue" on a piece-rate entry for the company). A role is a named set of permissions. There are no hard-coded role names in the code, so changing a role is a setting, not a release.
- The four Stylified roles (Owner, Manager, Supervisor, Munshi) and their matrix are in document 2, section 4.
- The server checks the permission for every command and every query. Hiding a button is only a convenience; it is never the control.
- **Supervisor stage scope.** The platform's scope list stays as it is. A supervisor's assigned stages are held as a small record in the piece-rate module, and the issue and return commands refuse a supervisor acting on a stage that is not theirs. This is tested with a second supervisor.

05 The data model

RECORD	WHAT IT HOLDS	RULES
Stage	A step in the line, in order (pasting, collar and cuff, stitching, button and kaj, finishing and press)	Stages are Stylified's data; the order is frozen once work exists
Lot	Number, name, design, fabric type, planned pieces, dates, status	Numbers are gapless and never reused; a closed lot is locked
Bundle	Number B-0001 onward, net pieces, size-mix note, the lot it belongs to	Numbers are gapless per workspace
Karigar or unit	Name, kind (in the factory or outside), contact, active	Retired, never deleted
Rate	Rupees per piece for a karigar at a stage, the wage basis, the date it applies from	History is kept; each return takes a snapshot of the rate used
Entry (issue or return)	Bundle, stage, karigar, pieces, due date, and for a return the split into good, rejected, rework and short	Append-only. A database check makes the four parts sum to the pieces returned. Corrections are reversals
Payment	Advance, recovery, deduction or payment, amount, mode, reference, reason	Append-only; amounts are whole paise, so there is no rounding drift
Stage assignment NEW	A supervisor and a stage	Set by the owner; checked by the commands
Approval request NEW	Kind (deduction, write-off, hold, close), subject, amount or pieces, requester, state, decision and reason	Decided once; above-limit requests need the owner
Evidence photo NEW	A file reference on a rejected or rework entry; a cover photo reference on a lot	Stored with company isolation; never a public link
Day close NEW	Supervisor, date, summary figures at the time, a note	Frozen once submitted

How the figures are made

Nothing on a dashboard is typed in. Pieces out, pieces waiting, good, rejected, rework, short, days at a stage, wages and balances are all computed from the entries and payments by one piece of logic, which is covered by automated tests that use the worked examples from your requirement sheet (for example 100 pieces issued, 94 good, 2 rejected, 1 rework, 2 short and 1 still open; and ₹48,000 over 960 good pieces is ₹50 a piece). A figure on a report always agrees with the entries it is built from.

06 Audit and corrections

- Every command records who did it, when, from which role, and what changed, in an audit trail the owner can read.
- Entries, payments and rate history cannot be updated or deleted by the application: a database rule rejects both. A wrong entry is cancelled by a **reversal** with a reason; the original and the reversal both stay visible.
- A reversal that would leave a later stage with more pieces than it received is refused.

07 Photographs

- A photograph is uploaded from the phone camera or a file, checked for type and size, stored in the company's isolated storage, and shown through a short-lived link only to users who may see the record.
- Pictures are resized for the screen so lists stay fast.

08 Backups and recovery

- A daily backup of the database and files, kept for at least 30 days, is part of the service (document 3, section 5). The mechanism (the hosting provider's backups plus our own nightly export) is configured and a **restore is rehearsed** on Stylified's workspace before go-live; that rehearsal is an acceptance criterion.
- Because corrections are reversals, a restore is needed only for loss or damage, not for ordinary mistakes.

09 Security summary

CONCERN	CONTROL
One company seeing another's data	Forced row-level security in the database; company taken from the verified membership; tested
A user doing more than their role allows	Server-side permission check on every command and query; tested
Altering history	Append-only ledgers enforced by the database; reversal only
Staff access to your data	Only to support you; each session recorded in your audit trail and time-limited
Secrets	Held in the hosting environment, never in code or in the database
Public links	The bundle QR opens a sign-in screen, then the bundle. It carries only the bundle's address, no figures or names

10 Speed

We measured the local build: a page made about 10 to 16 database calls, mostly shared overhead from sign-in and navigation rather than the page itself. We have already removed the repeated identity lookups (the first of several steps), added an instant top progress bar and press feedback on every card and button, and replaced the lone loading spinner with a page-shaped skeleton. The remaining planned steps are folding the layout's

queries into one, caching each user's navigation and permissions for about a minute, and narrowing the dashboard's queries as history grows. We will report measured times on Stylified's workspace before go-live, not estimates.

11 Testing

LAYER	WHAT IS COVERED
Logic tests	28 tests on the piece-rate calculations, using the requirement sheet's own examples
Database tests	23 tests against a real database: reconciliation, over-issue and over-return refusals, rework pool, the three wage bases, payment guards, reversal rules, concurrent entries, append-only rules, the owner role refused every write, company isolation
Platform tests	Identity, membership, tenant isolation and permission tests that every capability inherits
Browser checks	Every screen opened in dark and light on desktop and at 390 px, with the demonstration data, before go-live; defects are logged and fixed
Acceptance	The ten criteria in document 2, section 10, run with Stylified

12 What we are not claiming

- The piece-rate module has been run on fictional data on our own test environment. It has not yet run on Stylified's workspace or with Stylified's people.
- The new supervisor, approval, photograph and bilingual work in this project is a plan until it is built and passes its tests.
- Speed on the hosted service is not yet measured; the figures above are from a local build.
- Offline use, SMS or WhatsApp alerts, barcode scanning and the Phase 2 modules are not part of this solution.
- A deployment on Stylified's own Vercel and Supabase accounts is not built, not validated and not part of this solution.
